(57) **ABSTRACT**

Disclosed are a method, apparatus and system for instant message routing. The method includes: receiving a communication request from a source client to a destination client; acquiring the context associated with the source client and the destination client; and selecting a sub-user of the destination client for communication using a policy according to the context. When a source client requests communication with a virtual user, the method can route the communication request using a policy according to the context, to a sub-user of the virtual user which once communicated with the source client.

INSTANT MESSAGE (IM) ROUTING TO A VIRTUAL USER CONSISTING OF A GROUP OF POSSIBLE SUB-USERS ASSOCIATED WITH A COMMON IM IDENTITY

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of Chinese Patent Application No. 200710105573.0 filed 28 May 2007, which is hereby incorporated by reference.

BACKGROUND OF THE INVENTION

The present invention relates to the field of instant messaging, and more particularly, to a method, apparatus and system for instant message routing.

Instant messaging (IM) is a form of real-time communication between two or more people in which text, speech, and/or video is exchanged. As used herein, IM communications can include communications conducted using a chat based protocol, a text messaging based protocol, and/or a protocol specific to IM communications. Comparing with e-mails or phone, instant messaging has its unique advantages. For example, there is less interference in communication via instant messaging than communication in phone; most instant messaging systems allow users to set their presence status information on the client side to show whether or not they are available; and, it is unnecessary to reply immediately via instant messaging. Therefore, instant messaging becomes more and more popular in web applications and enterprise environment.

A current instant messaging system is composed of server (s) and clients. The functions of instant messaging server(s) in an instant messaging system are typically to collect client's status information, to initialize sessions with clients and to transmit an instant messaging session in common cases. On the client side, each end user can log on an instant messaging system with its own ID. When a user wants to communicate with another user, the source client in the instant messaging system sends a request for communication to the server. The server then transmits the request to the corresponding destination client and transmits response information from the destination client to the source client; thereby the communication between the source client and the destination client is set up.

Users in a traditional instant messaging system have the same capability, whereas users in some current instant messaging systems have unequally capability. For example, in an online shopping center using instant messaging, buyers and sellers are each able to use clients in the instant messaging system, with the former being source clients and the latter being destination clients. A seller may have a plurality of salesmen, namely sub-users, each of which has an IM account number, for example. Where a plurality of salesman of the seller is online at the same time, after a buyer communicates with one or more salesmen of the seller, for example, buys a product, the buyer wants to communicate with the same salesman (salesmen) once more according to a certain policy which might be, for example, selecting the latest salesman whom the buyer communicated with, selecting the currently freest salesman among the salesmen whom the buyer communicated with, selecting the salesman who is the nearest to the buyer's geographical location among the salesmen whom the buyer communicated with, or the like. However, the prior

2

art cannot solve the problem of selecting sub-users out of destination clients according to a policy.

BRIEF SUMMARY OF THE INVENTION

In view of the problem described above, the present invention provides a method, apparatus and system for instant message routing.

The present invention is able to route the communication request using a policy according to the context, to a sub-user of the destination client which once communicated with the source client, whenever a source client requests communication with a destination client.

According to a first aspect of the present invention, there is provided a method for instant message routing that includes: receiving a communication request from a source client to a destination client; acquiring the context associated with the source client and the destination client; and selecting a sub-user of the destination client for communication using a policy according to the context.

According to a second aspect of the present invention, there is provided an apparatus for instant message routing that includes: a receiver operable to receive a communication request from a source client to a destination client; an acquirer operable to acquire the context associated with the source client and the destination client; and a selector operable to select a sub-user of the destination client for communication using a policy according to the context.

According to a third aspect of the present invention, there is provided a system for instant message routing that includes: a source client operable to communicate with a destination client; a destination client comprising one or more sub-users and operable to have one sub-user thereof communicate with the source client; and a server operable to select a sub-user of the destination client for communication with the source client using a policy according to the context associated with the source client and the destination client.

Other features and advantages of the present invention will become apparent from the following detailed description of preferred embodiments illustrating the principles of the invention, when taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION ON THE SEVERAL VIEWS OF THE DRAWINGS

FIG. 1 is a schematic view of an instant messaging system according to an embodiment of the present invention;

FIG. 2 is a timing view of operations for setting up communication in the instant messaging system shown in FIG. 1;

FIG. 3 is a flowchart of a method for instant message routing according to an embodiment of the present invention; and

FIG. 4 is a block diagram of an apparatus for instant message routing according to an embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

The embodiments of the present invention will be described in detail.

It is to be understood that among the terms adopted in the present invention, common users and virtual users are different types of clients in an instant messaging system.

"Common users" are traditional users in an instant messaging system.

3

“Virtual users” are users in an instant messaging system, which has an associated profile of a common user, and which can contain one or more common users as a group of sub-users. When a common user communicates with a virtual user, the common user regards the virtual user as its communication partner, whereas it actually communicates with one of sub-users belonging to the virtual user, and typically it does not know which sub-user it is exactly communicating with.

“Sub-user” can be a common user in an instant messaging system, which may employ a common user ID (identifier) independent of the virtual user ID of the virtual user it belongs to or take a virtual user ID as its user ID without an independent user ID.

In the present invention, the functions of “server(s)” in an instant messaging system are to maintain communication between clients (for example, common users and virtual users including one or more sub-users) in the instant messaging system and store the related communication information, such as context.

“Context” can include a source client ID, a destination client ID, a destination client’s sub-user ID, personal information, geographical information, communication status information and communication history of a source client, geographical information, communication status information and communication history of a destination client, as well as geographical information and communication status information of a sub-user of a destination client. Communication status information includes a time stamp, bandwidth of communication, operating system information, and so on.

“Policy” is a setting for selecting a proper sub-user for communication according to the information contained in context. For example, policies may include: selecting an available sub-user with which the communication is the latest according to communication historical records in the context; selecting an available sub-user in the nearest geographical location according to the geographical location information in the context; selecting an available sub-user with the smallest load according to the load information in the context; selecting a sub-user by combining some policies according to different information in the context, and so on.

An example of an application scenario of the present invention will first be explained before the embodiments of the present application will be described in detail.

First, a common user A and a virtual user B log on to an instant messaging system. The common user A logs on in a conventional way, the details of which are omitted here. During log on, the virtual user B sends a logon request to a server. Upon receipt of the request, the server checks the user type of the virtual user B and learns that the user is a virtual user including N sub-users. Then, the server searches a table on which user information is recorded, gets information on the sub-users of the virtual user B, and acquires presence information and status information of each sub-user of the virtual user B to update the current presence information and status information of the virtual user B.

Next, the common user A communicates with the virtual user B via the server. Since the virtual user B is a group consisting of N sub-users, when the common user A requests communication with the virtual user B, it is actually communicating with one of sub-users of the virtual user B. Therefore, how to select a proper sub-user for communication with the common user A is a problem to be solved by the present invention.

FIG. 1 is a schematic view of an instant messaging system according to an embodiment of the present invention. A server helps a source client requesting connection setup to find a destination client the source client wants to communi-

4

cation with. Then, the communication is set up between these two clients. Thereafter, the two clients communicate directly without the server’s participation, or they communicate taking the server as a bridge (not shown in FIG. 1). In the example shown in FIG. 1, the destination client is a virtual user consisting of four sub-users, namely sub-user 1, sub-user 2, sub-user 3, and sub-user 4. Assuming that the source client has recently communicated with sub-user 1 of the destination client, when the source client wants to communicate with the destination client once more, the server will use a policy to select a sub-user of the destination client for communication with the source client according to the context-based routing method of the present invention, so that the source client can communicate with sub-user 1 other than sub-user 2, sub-user 3 or sub-user 4 of the destination client once more. Steps 101-106 of FIG. 1 will be further explained in FIG. 2.

FIG. 2 is a timing view of operations for setting up communication in the instant messaging system shown in FIG. 1. It should be noted that the context-based routing method of the present invention is implemented at the server side of the instant messaging system, as shown by the hexagon in FIG. 2.

In step 101, the source client receives a communication request from the outside and gets the ID of the destination client according to the requested content. In step 102, the source client sends a request to the server for communication with the destination client. Upon receipt of the request, the server acquires the context associated with the source client and the destination client, and uses the policy to select a sub-user of the destination client for communication according to the context. The selected sub-user is sub-user 1 of the destination client which has communicated with the source client recently. In step 103, the server transfers the communication request from the source client to sub-user 1 of the destination client, requesting communication therewith. In step 104, sub-user 1 of the destination client agrees to communicate with the source client, making an acknowledgement to the server. In step 105, the server transfers the response message indicating an acknowledgement of communication to the client. In step 106, the source client communicates with sub-user 1 with which a connection has been set up.

FIG. 3 is a flowchart of a method for instant message routing according to an embodiment of the present invention. The method corresponds to the processing performed by the server for selecting a sub-user of the destination client based on context between step 102 and step 103 in FIG. 2. The method of the present invention will be described in detail in terms of the flowchart of FIG. 3.

In step 301, a communication initiating request is received from a client. As described previously, in an instant messaging system, a user on the source client side initiates a communication request, and then the server receives the request and performs corresponding processing according to the content contained in the request. The communication request may include a variety of information, such as a source client ID, a destination client ID which the source client wants to communicate with, and so on.

In step 302, the destination client ID is obtained according to the received communication request. Upon receipt of the communication request from the source client, the server gets the destination client ID contained in the request, with that the source client wants to communicate.

In step 303, it is determined whether or not the destination client is available. Before communication is set up between the source client and the destination client, it is necessary to determine in advance whether or not the destination client is available.

Usually a traditional instant messaging system is provided with the function to support various statuses of a common user, like “online,” “busy,” “away,” “offline” etc. During the traditional processing for determining a client status, it is necessary to query a client status table stored on the server or other server-accessible storage medium, each record of the client status table including the ID of a client, the status of the client, and so on. For example, when the status of a destination client in one record is “online,” “busy,” and “away,” the destination client is regarded as available, and when its status is “offline,” the destination client is regarded as unavailable.

In contrast to a traditional instant messaging system, the present invention introduces a new kind of users, namely virtual user. A virtual user may comprise a plurality of common users as sub-users. Therefore, different from a common user, the status of a virtual user can have various definition methods. For example, the status of a virtual user can be defined as follows:

Virtual User “online,” i.e. one or more sub-users are “online”;

Virtual User “busy,” i.e. all the sub-users are “busy”, or some are “busy” while others are “offline” or “away”;

Virtual User “away,” i.e. all the sub-users are “away”, or some are “away” and others are “offline”;

Virtual User “offline,” i.e. all the sub-users are “offline.”

In the present invention, status information of both virtual users and common users is stored in the client status table. During the processing for determining a client status of the present invention, it is also necessary to query the client status table, each record of the client status table including the ID of a client (including a common user and a virtual user), the status of the client, and so on. In this embodiment, the client status table is stored on the server. Additionally, the client status table may be stored on other server-accessible storage medium. According to the status information of a client, various ways can be employed to determine whether or not the client is available. For example, when a destination client’s status in records is “online,” “busy” and “away,” the destination client is regarded as available, and when its status is “offline,” the destination client is regarded as unavailable. For another example, when a destination client’s status in records is “online,” the destination client is regarded as available, and when its status is “busy,” “away” and “offline,” the destination client is regarded as unavailable.

If the destination client is determined as available, the processing goes to step 304, otherwise the processing ends. In this embodiment, the status of sub-user 1 of the destination client is “online,” and the status of sub-user 2 is “offline,” and the status of sub-user 3 is “busy,” and the status of sub-user 4 is “online,” so the status of the destination client is “online.” And the processing goes to step 304.

In step 304, the type of the destination client is checked. In the present invention, the destination client might be a common user or a virtual user consisting of one or more sub-users. Different processing means are employed for different types of clients. Therefore, it is necessary to query a client type table stored on the server or other server-accessible storage medium. In the client type table there are recorded the ID of a client, the type of the client, and so on. The client type table and the client status table may be one same table or different tables stored separately. According to the client type table, the destination client can be searched and its type can be determined.

In step 305, it is determined whether or not the destination client is a virtual user. When the client is a virtual user, the flow goes to a subsequent step, i.e. step 306. When the client is not a virtual user, the flow goes to step 311. At this point, the

processing is performed using the prior art. The communication setup request is transferred to the destination client which is a common user, and then the processing ends. In this embodiment, the destination client is a virtual user which has sub-user 1 to 4. Therefore, the flow goes to step 306.

In step 306, context associated with the source client and the destination client is acquired. The context of the source client, the destination client with which communication was once set up and the sub-users thereof is stored in a context information database. The context information database may be located on the server or other server-accessible storage medium. In this embodiment, the context information database is located on the server. Context may comprise, for example, communication historical records including time stamps, source client IDs, destination client IDs and sub-user IDs, or other information associated with communication between a source client and a destination client. In step 306, for example, the context containing a source client ID can be obtained by taking the source client ID as a query keyword, and among the query results, the context containing a destination client ID can be obtained by taking the destination client ID as a query keyword.

In step 307, the latest communication historical records and the time stamps among the records are obtained according to the context. Table 1 shows the communication historical records contained in the context obtained in this embodiment.

TABLE 1

time	source client ID	destination client ID	sub-user ID	...
11:45:10, 1/16/2007	abc	XianFengShuDian	ShopAssistant1	...
14:23:49, 1/15/2007	abc	XianFengShuDian	ShopAssistant3	...
...

Table 1 shows two records. One is that a source client with the ID of abc communicated with sub-user 1, namely ShopAssistant1, of a destination client with the ID of XianFengShuDian, at 11:45:10 on Jan. 16, 2007. And the other is that a source client with the ID of abc communicated with sub-user 3, namely ShopAssistant3, of a destination client with the ID of XianFengShuDian, at 14:23:49 on Jan. 13, 2007.

In this embodiment, according to the context shown in Table 1, the communication performed at 11:45:10 on Jan. 16, 2007 of the first record is the latest communication historical record. In this communication record, the source client abc performed communication with sub-user 1, namely ShopAssistant1, of the destination client XianFengShuDian, and the time stamp is 11:45:10, Jan. 16, 2007.

In step 308, after the time stamp of the latest communication record is obtained, it is necessary to determine whether or not the record is valid. If the record is valid, the sub-user ID of the valid record is acquired. That is, the sub-user of the valid record is obtained. In this embodiment, assume this step was performed at 13:05:55 on Jan. 16, 2007. Additionally, assume in the instant messaging system of the present invention, the expiration time for judging whether a record is valid is one day, i.e. 24 hours. Since the first record was no more than one day, it is valid. Hence, the ID ShopAssistant1, sub-user 1 of the destination client XianFengShuDian, which is associated with the source client abc is obtained, and then the flow goes to step 309.

It is to be understood that in any instant messaging system, different expiration times for judging whether or not a record is valid can be defined, such as one hour, two hours, one week, one month etc.

If the expiration time for judging whether or not a record is valid is one hour, the first record is invalid since it was one hour 20 minutes and 45 seconds ago. Hence, other policy can be selected to select a sub-user.

In another embodiment of the present invention, if the latest communication historical record is determined as invalid, then according to sub-users' load information in the context, an available sub-user with the smallest load can be selected as the sub-user with which the source client communicates.

In a further embodiment of the present invention, if the latest communication historical record is determined as invalid, then according to sub-users' geographical location information in the context, an available sub-user in the nearest geographical location can be selected as the sub-user with which the source client communicates.

In step 309, if obtained sub-user 1, namely ShopAssistant1 is determined as available, the sub-user is selected to communicate with the source client. In this embodiment, sub-user 1 to 4 are all common users, so the method for judging the status of a sub-user is the same as that for determining the status of a common user in the prior art. The status of sub-users is stored in a sub-user status table on the server or other server-accessible storage medium, and each record of the sub-user status table may include the ID of a sub-user, the client ID which the sub-user belongs to, the status of the sub-user, and so on. According to the status of the sub-user, including "online," "busy," "away" and "offline" for example, various means can be employed to define whether or not the sub-user is available. For example, when the status of a sub-user in the sub-user status table is "online," "busy" or "away," the destination client is regarded as available, so the sub-user is selected to communicate with the source client. When its status is "offline," the destination client is regarded as unavailable, so other policy can be used to select a sub-user, such as based on the smallest load or the nearest geographical location according to the context.

In this embodiment, the status of sub-user 1, namely ShopAssistant1 is "online." Therefore, the sub-user is determined as available, and sub-user 1, namely ShopAssistant1 is selected as the sub-user of the destination client (XianFengShuDian) to communicate with the source client abc.

In step 310, context associated with the source client and the destination client and contained in the context information database is updated. For example, a record that the source client abc communicated with sub-user 1, namely ShopAssistant1 of the destination client XianFengShuDian at 13:05:55 on Jan. 16, 2007, is added to the context information database, just as shown by the first record in Table 2. Then, the processing ends.

TABLE 2

time	source client ID	destination client ID	sub-user ID	...
13:05:55, 1/16/2007	abc	XianFengShuDian	ShopAssistant1	...
11:45:10, 1/16/2007	abc	XianFengShuDian	ShopAssistant1	...
14:23:49, 1/15/2007	abc	XianFengShuDian	ShopAssistant3	...
...

It is to be understood that after the context associated with the source client and the destination client is acquired, policies of the present invention can include a variety of other possible policies besides selecting an available sub-user with which the communication is the latest according to steps 307 and 308 shown in FIG. 3.

In another embodiment of the present invention, after the context associated with the source client and the destination client is acquired, a sub-user with the smallest load can be selected according to sub-users' load information in the context, and when the sub-user is determined as available, it is taken as the sub-user with which the source client communicates.

In a further embodiment of the present invention, after the context associated with the source client and the destination client is acquired, a sub-user in the nearest geographical location can be selected according to sub-users' geographical location information in the context, and when the sub-user is determined as available, it is taken as the sub-user with which the source client communicates.

Additionally, a proper sub-user can be selected to communicate with the source client according to age, gender or level in users' personal information of the source client. Other possible schemes include selecting a sub-user according to the period and bandwidth of communication or a combination of a variety of information. Those of ordinary skilled in the art can devise different schemes to select a sub-user according to the teaching of the present invention, and dynamically adjust the policy to select a sub-user.

FIG. 4 is a block diagram of an instant message routing apparatus 400 according to an embodiment of the present invention. Apparatus 400 comprises: a receiver 410, an acquirer 420 and a selector 430. Apparatus 400 may further comprise an updater 440. Moreover, apparatus 400 may comprise a context information database 450 and a policy database 460.

Receiver 410 is operable to receive a communication request from a source client to a destination client.

Acquirer 420 is operable to acquire the context associated with the source client and the destination client. Acquirer 420 may comprise means for determining whether or not the destination client is a virtual user and acquiring the context associated with the source client when the destination client is a virtual user.

Selector 430 is operable to select a sub-user of the destination client for communication using a policy according to said context. Selector 430 may comprise: means for acquiring the latest communication historical record in the context, to obtain IDs of the valid sub-users in the record and to select an available sub-user among the valid sub-users; means for acquiring sub-users' geographical location information in the context and selecting an available sub-user in the nearest geographical location; or means for acquiring sub-users' load information in the context and selecting an available sub-user with the smallest load.

Updater 440 is operable to update the context in the context information database according to a sub-user selection result from the selector.

Context information database 450 is operable to store the context.

Policy database 460 is operable to store policies for selecting a sub-user.

The present invention further discloses an instant message routing system comprising: a source client operable to communicate with a destination client; a destination client comprising one or more sub-users and operable to have one sub-user thereof communicate with the source client; a server

9

operable to select a sub-user of the destination client for communication with the source client using a policy according to the context associated with the source client and the destination client. The server may comprise: a receiver **410**, an acquirer **420** and a selector **430**. The server may further comprise an updater. Moreover, the server may comprise a context information database **450** and a policy database **460**.

It is to be understood that the method, apparatus and system for instant message routing of the present invention can also be applied to P2P instant messaging. During P2P instant messaging, the procedure for setting up underlying communication links between two clients might be different from that in a traditional instant messaging system, for example, the link information needs to be propagated over a P2P network. However, the method and apparatus for instant message routing of the present invention operate on the application layer of the instant messaging system to select a sub-user. Therefore, the method, apparatus and system of the present invention are also applicable to a P2P instant messaging system.

The method of the present invention is adapted to communication with a virtual user including a plurality of sub-users. Specifically, the method of the present invention can select for a source client a sub-user of the virtual user to communicate therewith using a policy according to the context containing information on the sub-user of the virtual user which once communicated with the source client. Therefore, after communication with a sub-user of the virtual user, the source client can communicate with the desired sub-user once more without the need to set up communication with a different sub-user of the virtual user each time.

The present invention further relates to a computer program product including codes for: receiving a communication request from a source client to a destination client; acquiring the context associated with the source client and the destination client; and selecting a sub-user of the destination client for communication using a policy according to the context.

Such a computer program product can be stored on a storage carrier.

While the foregoing has been with reference to specific embodiments of the invention, it will be appreciated by those skilled in the art that these are illustrations only and that changes in these embodiments can be made without departing from the principles of the invention, the scope of which is defined by the appended claims.

The invention claimed is:

1. A method for initiating an instant messaging communication setup, comprising the steps of:

receiving, at an instant messaging server, a communication request for an instant messaging communication session from a source client, the request indicating a destination client;

determining, by the instant messaging server, responsive to receiving the communication request, whether the destination client corresponds to either a common user or a virtual user, wherein a common user is a unique user to which instant messaging requests directed to the common user are routed, wherein the virtual user corresponds to a plurality of sub-users to which requests directed to the virtual user are selectively routed;

responsive to a determination that the destination client is the common user, establishing the instant messaging communication session between the source client and the common user;

responsive to a determination that the destination client is the virtual user:

10

(a) acquiring, by the instant messaging server, a context associated with said source client and said destination client, the context including information stored in a medium accessible by the instant messaging server prior to receiving the request, wherein said context comprises communication history information including a most recent communication between the source client and the destination client, a time stamp of the most recent communication, and a historic one of the sub-users of the virtual user that handled the most recent communication;

(b) selecting one of the plurality of sub-users associated with said destination client for the instant messaging session, the selecting is performed according to a policy using information in said context, wherein per the policy said method further comprises:

determining, at the instant messaging server, an expiration time used by the instant messaging server for judging whether the most recent record is valid for biasing routing of the communication request;

responsive to a determination that the most recent record is valid, selecting the historic one of the sub-users for the instant messaging session; and responsive to the determination that the most recent record is not valid, selecting an available one of the sub-users with a smallest load for the instant messaging session.

2. The method according to claim **1**, wherein the instant messaging server utilizes a plurality of different policies for selecting which of the sub-users is selected to handle incoming requests for the virtual users, said plurality of different policies including the policy referenced hereafter as a first policy, a second policy, and a third policy:

said second policy comprising:

acquiring sub-users' geographical location information in said context;

selecting an available sub-user in the nearest geographical location;

said third policy comprising:

acquiring sub-users' load information in said context;

selecting an available sub-user with the smallest load.

3. The method according to claim **1**, further comprising: updating the context according to said sub-user selection result.

4. The method according to claim **1**, wherein the selecting comprises:

acquiring a latest communication historical record in the context;

obtaining valid sub-users' IDs of the record; and

selecting an available sub-user among the valid sub-users.

5. The method according to claim **1**, wherein the selecting comprises:

acquiring sub-users' geographical location information in said context; and

selecting an available sub-user, assuming more than one of the sub-users has communicated with the source client within the expiration time, in the nearest geographical location to said source client.

6. The method according to claim **1**, wherein the method further comprises:

determining whether the destination client is available before establishing the communication between the source client and the destination client.

7. The method according to claim **1**, wherein the method further comprises:

responsive to determining that the destination client is a virtual client, determining a status of the virtual client.

11

8. The method according to claim 1, wherein the method further comprises:

determining whether the context is valid;
acquiring a second context associated with a second policy different from the policy for selecting one of a plurality of different sub-user of said destination client, if the context is determined as invalid.

9. An apparatus for instant messaging, comprising:
one or more processors;

one or more memories storing program instructions executed by at least one of the one or more processors;
a receiver, comprising at least a subset of the program instructions, operable to receive a communication request from a source client, the request indicating a destination client;

an acquirer, comprising at least a subset of the program instructions, operable to determine whether the destination client corresponds to either a common user or a virtual user, wherein a common user is a unique user to which instant messaging requests directed to the common user are routed, wherein the virtual user corresponds to a plurality of sub-users to which requests directed to the virtual user are selectively routed, and responsive to determining that the destination client is the common user, establishing the instant messaging communication session between the source client and the common user, and responsive to determining that the destination client is the virtual user;

acquire a context associated with said source client and said destination client, the context including information stored in a medium accessible by the apparatus prior to the receiver receiving the request wherein said context comprises communication history information including a most recent communication between the source client and the destination client, a time stamp of the most recent communication, and a historic one of the sub-users of the virtual user that handled the most recent communication; and

a selector, comprising at least a subset of the program instructions, operable to select one of a plurality of different sub-user of said destination client for communication according to a policy using information in said context, wherein per the policy said selector:

determines, at the instant messaging server, an expiration time used by the instant messaging server for judging whether the most recent record is valid for biasing routing of the communication request;

responsive to a determination that the most recent record is valid, selects the historic one of the sub-users for the instant messaging session; and

responsive to the determination that the most recent record is not valid, selects an available sub-user with a smallest load for the instant messaging session.

10. The apparatus according to claim 9, further comprising:

a context information database operable to store said context; and

a policy database operable to store said policy.

11. The apparatus according to claim 9, wherein said selector utilizes a plurality of different policies for selecting which of the sub-users is selected to handle incoming requests for the virtual users, said plurality of different policies including the policy referenced hereafter as a first policy, a second policy, and a third policy:

12

said second policy comprising:

acquiring sub-users' geographical location information in the context in said context information database, and selecting an available sub-user in the nearest geographical location;

said third policy comprising:

acquiring sub-users' load information in the context in said context information database, and selecting an available sub-user with the smallest load.

12. The apparatus according to claim 9, further comprising:

an updater operable to update the context in said context information database according to the sub-user selection result from said selector.

13. A system for instant messaging, comprising:

one or more processors;

one or more memories storing program instructions executed by at least one of the one or more processors;
a source client, comprising at least one of the one or more memories and comprising at least one of the one or more processors, operable to communicate with a destination client;

the destination client, comprising at least one of the one or more memories and comprising at least one of the one or more processors; and

a server, comprising at least one of the one or more memories and comprising at least one of the one or more processors, operable to:

receive a communication request for an instant messaging communication session from a source client, the request indicating the destination client;

determine, responsive to receiving the communication request, whether the destination client corresponds to either a common user or a virtual user, wherein a common user is a unique user to which instant messaging requests directed to the common user are routed, wherein the virtual user corresponds to a plurality of sub-users to which requests directed to the virtual user are selectively routed;

responsive to a determination that the destination client is the common user, establish the instant messaging communication session between the source client and the common user;

responsive to a determination that the destination client is the virtual user:

(a) acquire a context associated with said source client and said destination client, the context including information stored in a medium accessible by the instant messaging server prior to receiving the request, wherein said context comprises communication history information including a most recent communication between the source client and the destination client, a time stamp of the most recent communication, and a historic one of the sub-users of the virtual user that handled the most recent communication;

(b) select one of the plurality of sub-users associated with said destination client for the instant messaging session, the selecting is performed according to a policy using information in said context, wherein per the policy said server:

determines an expiration time used by the instant messaging server for judging whether the most recent record is valid for biasing routing of the communication request;

13

responsive to a determination that the most recent record is valid, selects the historic one of the sub-users for the instant messaging session; and responsive to the determination that the most recent record is not valid, selects an available sub-user with a smallest load for the instant messaging session.

14. The system according to claim **13**, wherein said server further comprises:

a receiver operable to receive a communication request from the source client to the destination client;
 an acquirer operable to acquire the context associated with said source client and said destination client; and
 a selector operable to select a sub-user of said destination client for communication according to the policy using information in said context.

15. The system according to claim **14**, wherein said acquirer further comprises:

computer program product configured to cause a computing device to determine whether said destination client is the virtual client and configured to acquire the context associated with said source client when said destination client is the virtual client.

14

16. The system according to claim **14**, wherein said selector utilizes a plurality of different policies for selecting which of the sub-users is selected to handle incoming requests for the virtual users, said plurality of different policies including the policy referenced hereafter as a first policy;

said second policy comprising:

acquiring sub-users' geographical location information in said context, and selecting an available sub-user in the nearest geographical location;

said third policy comprising:

acquiring sub-users' load information in said context, and selecting an available sub-user with the smallest load.

17. The system according to claim **13**, wherein said server further comprises:

a context information database operable to store said context; and

a policy database operable to store said policy.

18. The system according to claim **13**, wherein said server further comprises:

an updater operable to update the context in said context information database according to the sub-user selection result from said selector.
